# Evolutionary Computation

- **= Population-based, stochastic search algorithms inspired by mechanisms of natural evolution**
- EC part of Computational Intelligence
- Evolution viewed as search algorithm
- Natural evolution only used as metaphor for designing computational problem solving systems
- No modelling of natural evolution ( $\neq$  evolutionary biology)

<span id="page-3-0"></span>メロトメ 倒 トメ 君 トメ 君 トー

## Key concepts of a Darwinian system

- **1** Information Structures
- <sup>2</sup> Copies
- <sup>3</sup> Variation
- <sup>4</sup> Competition
- **5** Inheritance

<span id="page-4-0"></span>E

イロト イ押 トイヨ トイヨ トー

## Evolutionary algorithm

#### $\mathbf{0} \cdot P(0) \leftarrow$  Generate-Random-Population()

- $\bullet$  P(0)  $\leftarrow$  Evaluate-Population(P(0))
- <sup>3</sup> **while** Not-Terminated? **do**

$$
\mathbf{D} \ \mathbf{P}^s \left( \mathbf{t} \right) \ \leftarrow \ \mathsf{Select-Mates} \left( \mathbf{P} \left( \mathbf{t} \right) \right)
$$

- $P^{o}(t) \leftarrow$  Generate-Offspring( $P^{s}(t)$ )
- $P^{\circ}(t) \leftarrow$  Evaluate-Population( $P^{\circ}(t)$ )
- $\bullet$  P(t+1)  $\leftarrow$  Select-Fittest( $P^0$ (t)  $\cup$  P(t))  $\bullet$  t  $\leftarrow$  t + 1

#### $\bullet$  **return**  $P(t)$

# Darwinian process characteristics:  $\Rightarrow$  Evolutionary Algorithm

#### <sup>1</sup> **Information structures:**

 $\Rightarrow$  e.g. binary strings, real-valued vectors, programs, ...

### <sup>2</sup> **Copies:**

 $\Rightarrow$  selection algorithm

<sup>3</sup> **Variation:**

 $\Rightarrow$  mutation & crossover operators

<sup>4</sup> **Competition:**

 $\Rightarrow$  fitness based selection + fixed sized population

### <sup>5</sup> **Inheritance:**

⇒ Partial variation should lead to fitness correlation between parents and offspring

<span id="page-7-0"></span>イロト イ部 トイヨ トイヨ トーヨ

**Neo-Darwinism**

**Genetic Algorithm**

- \* user: string representation and function **f**
- \* GA: string manipulation
	- **Exercise:** copy better strings
	- **variation:** generate new strings

<span id="page-8-0"></span>イロトメ 倒 トメ 君 トメ 君 トー

Selection methods: fitness proportionate selection

• Probability  $P_i$  of selecting individual *i* with fitness value  $F_i$ 

$$
P_i = \frac{F_i}{\sum_{j=1}^{N} F_j}
$$
 (N: population size)

Expected number of copies *N<sup>i</sup>* of individual *i*

$$
N_i = N \times P_i = \frac{F_i}{\overline{F}}
$$
 ( $\overline{F}$ : population mean fitness)

- Number of individuals with above average fitness increases
- Problems:
	- <sup>1</sup> Too much selection pressure if single individual has much higher fitness than the others in the population
	- <sup>2</sup> Loss of selection pressure when all fitness values converge to similar values

<span id="page-9-0"></span>イロト イ押 トイヨ トイヨ トーヨ

## Selection methods: ranked based

Selection based on relative fitness as opposed to absolute fitness

- **1** Truncation selection
	- $\triangleright$  Sort the population according to the fitness values
	- Select the top  $\tau\%$
	- ► Copy each selected individual  $\frac{100}{\tau}$  times
- <sup>2</sup> Tournament selection
	- ► Select best individual from *K* randomly selected individuals (preferably selected without replacement)
	- $\blacktriangleright$  Hold *N* tournaments to select *N* parent solutions

Selection pressure can be tuned by changing the truncation threshold  $\tau$ or the tournament size *K*

<span id="page-10-0"></span>イロト イ部 トイヨ トイヨ トーヨ

## Variation methods: mutation & crossover

#### **1** mutation

### {1111111111 ⇒ {1111111011

(small perturbations should be more likely than large ones)

#### crossover

2-point crossover: 1111111111 <sup>0000000000</sup> <sup>⇒</sup> 1111000011 0000111100 uniform crossover: 1111111111 <sup>0000000000</sup> <sup>⇒</sup> 1001110101 0110001010

<span id="page-11-0"></span>す ロ ト す 御 ト す 産 ト す 産 ト 。

# Toy example

$$
x \in [0,31] : f(x) = x^2
$$
  
binary integer representation:  $x_i \in \{0, 1\}$   

$$
x = x_1 * 2^4 + x_2 * 2^3 + x_3 * 2^2 + x_4 * 2^1 + x_5 * 2^0
$$

• Initial Random Population:

 $10010 : 18^2 = 324$  $01100 : 12^2 = 144$  $01001 : 9^2 = 81$  $10100 : 20^2 = 400$  $01000 : 8^2 = 64$  $00111 : 7^2 = 49$ population mean fitness  $\bar{f}(0) = 177$ 

<span id="page-12-0"></span>G.

イロト イ押 トイヨ トイヨ トー

#### • Generation 1:

#### tournament selection, 1-point crossover, mutation

Parent population mean fitness  $\bar{f}(1) = 383$ 

<span id="page-13-0"></span>イロト イ押 トイヨ トイヨ トーヨ

#### • Generation 3:

Parent population mean fitness  $\bar{f}(3) = 762$ 

<span id="page-14-0"></span>メロトメ 御 トメ ミトメ ミトリ 毛

### Schemata

 $\bullet$  Schema = similarity subset

```
11\#\#0 = \{11000, 11010, 11100, 11110\}
```
How does the number of solutions that are member of particular schemata change in successive populations ?

<span id="page-15-0"></span>イロト イ押 トイヨ トイヨ トー

## Schemata definitions

- $o(h)$ : schema order = number of fixed values:  $o(11 \# 0) = 3$
- $\delta(h)$ : schema length = distance between leftmost and rightmost fixed position:  $\delta(\#11\# \#0) = 4$
- $\bullet$   $m(h, t)$ : number of schema h instances at generation t
- $f(h,t) = \sum_{i \in P} f_i$ : schema fitness is average fitness of individual members

<span id="page-16-0"></span>イロト イ押 トイヨ トイヨ トーヨ

## Schemata competition

- **•** key issue: changing number of schemata members in successive **population**.
- fit schemata increase in proportion by selection.
- Schemata compete in their respective partitioning:

##*f*#*f* : ##0#0, ##0#1, ##1#0, ##1#1

Mutation and crossover viewed as destructive operators for the fit schemata.

<span id="page-17-0"></span>K ロ > K 個 > K 差 > K 差 > → 差

# Schema growth by selection

• Reproduction ratio  $\phi(h, t)$ 

$$
\boxed{\phi(h,t) = \frac{m(h,t^s)}{m(h,t)}}
$$

### **proportionate selection**

- **Probability individual** *i* **selected:**  $\frac{f_i}{\sum f_i}$  (*f<sub>i</sub>*: fitness ind. i)
- Expected number of copies of ind.  $i: \frac{f_i}{\sum f_i} N = \frac{f_i}{f(i)}$ *f* (*t*)

(N: population size)

<span id="page-18-0"></span>イロト イ部 トイヨ トイヨ トーヨ

▶ Expected number of copies of schema *h* members:

$$
m(h, ts) = m(h, t)\phi(h, t) = m(h, t)\frac{f(h, t)}{\bar{f}(t)}
$$

#### **tournament selection**

 $\triangleright$  tournament size *K*: 0 ≤  $\phi(h, t)$  ≤ *K* 

# Schema disruption by mutation

- probability bit flipped: *p<sup>m</sup>*
- schema *h* survives iff all the bit values are *not* mutated

$$
p_{survival} = (1 - p_m)^{o(h)}
$$

• for small values  $p_m \ll 1$ 

$$
(1-p_m)^{o(h)} \approx 1-o(h).p_m
$$

• disruption factor  $\epsilon(h, t)$  by mutation:

$$
\epsilon(h,t)=o(h).p_m
$$

<span id="page-19-0"></span>←ロト ( 伊 ) → ( ヨ ) → (ヨ ) →

# Schema disruption by recombination

- probability crossover applied  $p_c$
- **1-point crossover**
	- $\triangleright$  schema *h* survives iff cutpoint *not* within schema length  $\delta$ :

$$
p_{survival} = 1 - \frac{\delta(h,t)}{l-1}
$$

- **uniform crossover** (bit swap probability: *px*)
	- $\triangleright$  schema *h* survives iff none or all bits swapped together

$$
p_{survival} = p_x^{o(h)} + (1 - p_x)^{o(h)}
$$

• disruption factor  $\epsilon(h, t)$  by recombination:

$$
\boxed{\epsilon(h,t) = p_c.(1-p_{survival})}
$$

<span id="page-20-0"></span>(*pc*: probability of applying crosso[ver\)](#page-19-0) イロト イ押 トイヨ トイヨ トー

### Schema Theorem

• Selection, mutation, and recombination combined:  $\vert m(h, t + 1) \geq m(h, t) \phi(h, t) [1 - \epsilon(h, t)] \vert$ net growth factor:  $\gamma(h,t) = \frac{m(h,t+1)}{m(h,t)}$ 

$$
\gamma(h,t) \geq \phi(h,t)[1-\epsilon(h,t)]
$$

schemata with  $\gamma(h, t) > 1$  increase in proportion schemata with  $\gamma(h, t) < 1$  decrease in proportion

<span id="page-21-0"></span>K ロ > K 個 > K 差 > K 差 > → 差

## Schema Theorem cont'd

- low order, high performance schemata receive exponentially (geometrically) increasing trials → **building blocks**
- according to the k-armed bandit analogy this strategy is near optimal (Holland, 1975)
- happens in an implicit parallel way
	- $\rightarrow$  only the short, low-order schemata are processed reliably
- enough samples present for statistically reliable information
- enough samples survive the disruption of variation operators

<span id="page-22-0"></span>イロトメ 御 トメ ミトメ ミトリ 毛

# Building Blocks

### <span id="page-23-0"></span>**Building block hypothesis**

= building blocks can be juxtaposed to form near optimal solutions

#### **Consequences**

- <sup>1</sup> schema sampling is a statistical decision process: **variance considerations**
- <sup>2</sup> building blocks must be juxtaposed before convergence: **mixing analysis**
- <sup>3</sup> low order schemata might give misleading information: **deceptive problems** メロトメ 倒 トメ 君 トメ 君 トー
