**Automated manufacturing** 

### **CAD/CAM systems**

CAD/CAM systems allow you to design objects and test how they can be constructed

Many objects are constructed used a mold

# Casting

### Casting

A general question: Given an object, can it be made with a particular design process?

For casting, can the object be removed from its cast without breaking the cast?

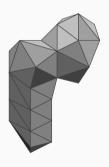

## Casting

Objects to be made are 3D polyhedra

The boundary is like a planar graph, but the coordinates of vertices are 3D

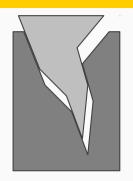

We can use a doubly-connected edge list with three coordinates in each vertex object

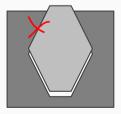

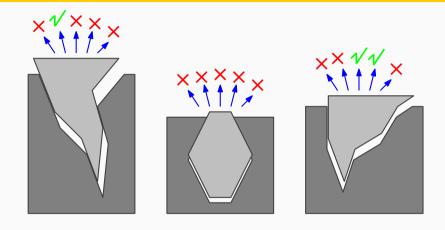

# Introduction

Casting in 2D

First the 2D version: can we remove a 2D polygon from a mold?

Certain removal directions may be good while others are not

What top facet should we use?

When can we even begin to move the object out?

What kind of movements do we allow?

Assume the top facet is fixed; we can try all

An edge of the polygon should not *directly* run into the coinciding mold edge

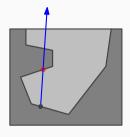

Let us consider translations only

. . .

**Observe:** For a given top facet, if the object can be translated over some (small) distance, then it can be translated all the way out

Consider a point p that at first translates away from its mold side, but later runs into the mold

A polygon can be removed from its cast *by a single translation* if and only if there is a direction so that every polygon edge does not cross the adjacent mold edge

Sequences of translations do not help; we would not be able to construct more shapes than by a single translation

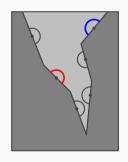

#### **Circle of directions**

We need a representation of directions in 2D

Every polygon edge requires the removal direction to be in a semi-circle

⇒ compute the common intersection of a set of circular intervals (semi-circles)

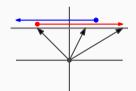

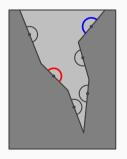

#### **Line of directions**

We only need to represent upward directions: we can use points on the line y=1

Every polygon edge requires the removal direction to be in a half-line

 $\Rightarrow$  compute the common intersection of a set of half-lines in 1D

#### **Common intersection of half-lines**

The common intersection of a set of half-lines in 1D:

- Determine the endpoint  $p_l$  of the rightmost left-bounded half-line
- Determine the endpoint  $p_r$  of the leftmost right-bounded half-line
- The common intersection is  $\left[p_l,p_r\right]$  (can be empty)

#### **Common intersection of half-lines**

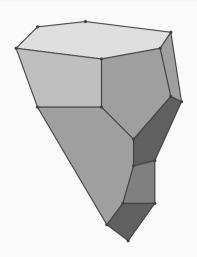

The algorithm takes only O(n) time for n half-lines

Note: we need not sort the endpoints

Can we do something similar in 3D?

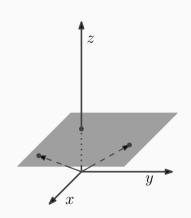

Again each facet must not move into the corresponding mold facet

## **Representing directions in 3D**

The circle of directions for 2D becomes a sphere of directions for 3D; the line of directions for 2D becomes a plane of directions for 3D: take z=1

Which directions represented in the plane does a facet rule out as removal directions?

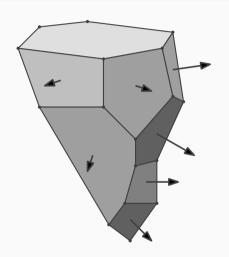

#### **Directions in 3D**

Consider the outward normal vectors of all facets

An allowed removal direction must make an angle of at least  $\pi/2$  with every facet (except the topmost one)

 $\Rightarrow$  every facet in 3D makes a half-plane in z=1 invalid

# Common intersection computation

## **Common intersection of half-planes**

The problem of deciding castability of a polyhedron with n facets, with a given top facet, where the polyhedron must be removed from the cast by a single translation, can be solved by computing the common intersection of n-1 half-planes

**Problem:** common intersection of half-planes in the plane?

# **Common intersection of half-planes**

Half-planes in the plane:

• 
$$y \ge m \cdot x + c$$

• 
$$y \le m \cdot x + c$$

# Common intersection computation

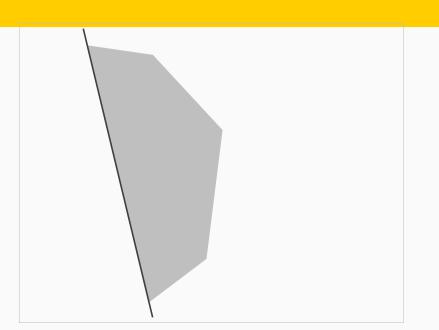

Incremental common intersection

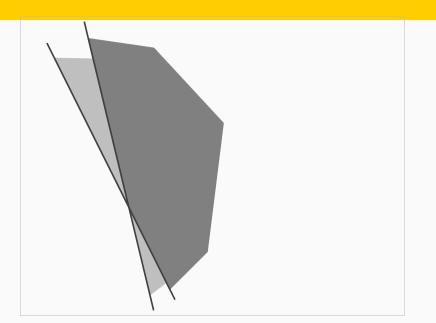

# An approach

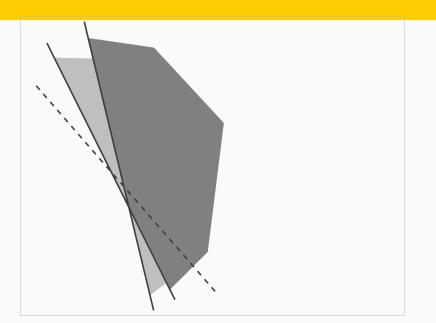

Take the first set:

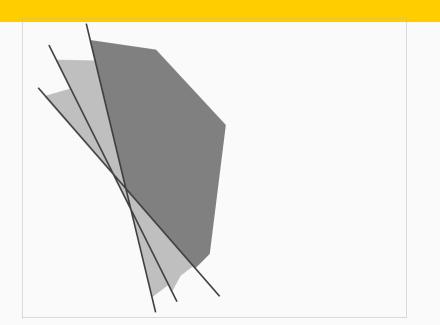

• 
$$y \ge m \cdot x + c$$

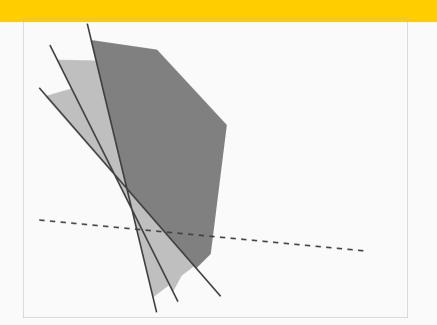

Sort by angle, and add incrementally

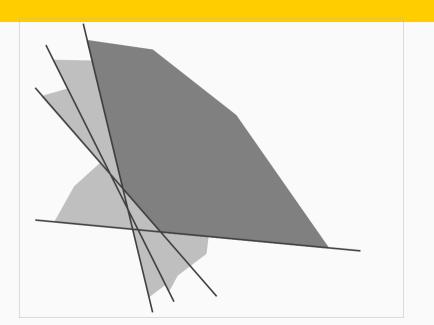

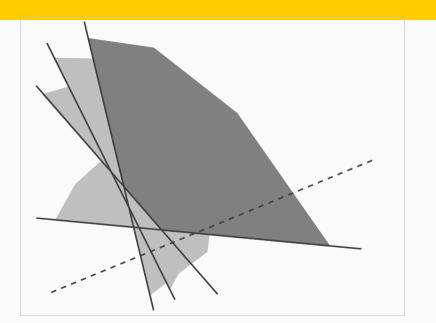

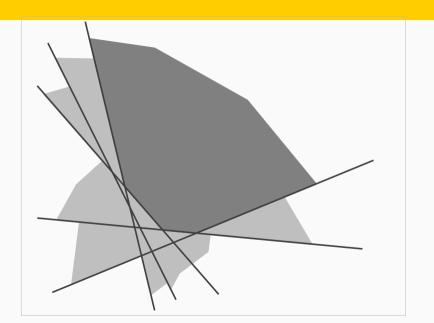

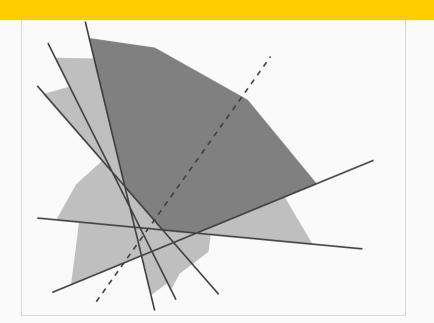

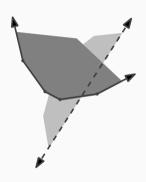

The boundary of the valid region is a polygonal convex chain that is unbounded at both sides

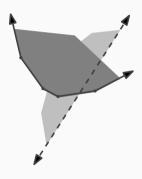

The next half-plane has a steeper bounding line and will always contribute to the next valid region

Maintain the contributing bounding lines in increasing angular order

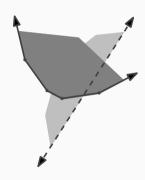

For the new half-plane, remove any no longer contributing bounding lines from the end

Then add the line bounding the new half-plane

After sorting on angle, this takes only O(n) time

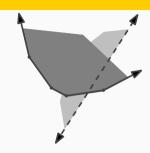

**Question:** Why?

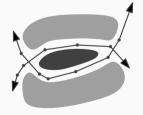

After sorting on angle, this takes only O(n) time

The half-planes bounded from above give a similar chain

Intersecting the two chains is simple with a left-to-right scan

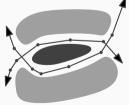

Half-planes with vertical bounding lines can be added by restricting the region even more

This can also be done in linear time

#### Result

**Theorem:** The common intersection of n half-planes in the plane can be computed in  $O(n\log n)$  time

The common intersection may be empty, or a convex polygon that can be bounded or unbounded

### **Back to casting**

The common intersection of half-planes cannot be computed faster (we are sorting the lines along the boundary)

The region we compute represents *all mold removal directions* . . .

... but to determine castability, we only need one!

# Linear programming in 2D

# **Linear programming**

We will find the *lowest* point in the common intersection

Notice that half-planes are linear constraints

#### Minimize *y*

## Subject to

$$y \ge m_1 \cdot x + c_1$$

$$y \ge m_2 \cdot x + c_2$$

$$\vdots$$

$$y \ge m_i \cdot x + c_i$$

$$y \le m_{i+1} \cdot x + c_{i+1}$$

$$\vdots$$

$$y \le m_n \cdot x + c_n$$

# **Linear programming**

Minimize 
$$c_1 \cdot x_1 + \cdots + c_k \cdot x_k$$

#### Subject to

$$a_{1,1} \cdot x_1 + \dots + a_{k,1} \cdot x_k \le b_1$$
  
 $a_{1,2} \cdot x_1 + \dots + a_{k,2} \cdot x_k \le b_2$   
 $\vdots$   
 $a_{1,n} \cdot x_1 + \dots + a_{k,n} \cdot x_k \le b_n$ 

where  $a_{1,1},\ldots,a_{k,n},\ b_1,\ldots,b_n,\ c_1,\ldots,c_k$  are given coefficients

This is LP with k unknowns (dimensions) and n inequalities

**Question:** Where are the  $\geq$  inequalities?

# Linear programming in 2D

**Terminology** 

## **Terminology**

LP with k unknowns (dimensions) and n inequalities: k-dimensional linear programming

The subspace that is the common intersection is the feasible region. If it is empty, the LP is infeasible

The vector  $(c_1,\ldots,c_k)^T$  is the objective vector or cost vector

If the LP has solutions with arbitrarily low cost, then the LP is unbounded

Note: The feasible region may be unbounded while the LP is bounded

# Linear programming in 2D

LP for casting

## LP for casting

LP for determining castability of 3D polyhedra is 2-dimensional linear programming with n constraints

We only want to decide feasibility, so we can choose any objective function

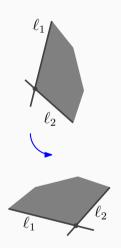

We will make it easy for ourselves

Let  $h_1,\ldots,h_n$  be the constraints and  $\ell_1,\ldots,\ell_n$  their bounding lines

Find any two constraints  $h_1$  and  $h_2$  where  $\ell_1$  and  $\ell_2$  are non-parallel

Rotate  $h_1$  and  $h_2$  over an angle  $\alpha$  around the origin to make  $\ell_1 \cap \ell_2$  the optimal solution for the objective function that minimizes y

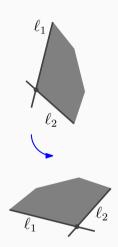

Rotate all other constraints over lpha too

Solve the LP with the rotated constraints

If the rotated LP is infeasible, then so is the unrotated version

If the rotated LP gives an optimal solution  $(p_x,p_y)$ , then rotate it over an angle  $-\alpha$  around the origin to get the removal direction for the original position of the polyhedron

The algorithm adds the constraints  $h_3,\dots,h_n$  incrementally and maintains the optimum so far

Let 
$$H_i = \{h_1, \ldots, h_i\}$$

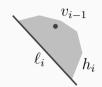

Let  $v_i$  be the optimum for  $H_i$  (unless we already have infeasibility)

# LP for casting

The incremental step: suppose we know  $v_{i-1}$  and want to add  $h_i$ 

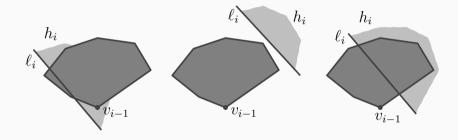

- If  $v_{i-1} \in h_i$ , then  $v_i = v_{i-1}$
- If  $v_{i-1} \not\in h_i$ , then either the LP is infeasible, or  $v_i$  lies on  $\ell_i$

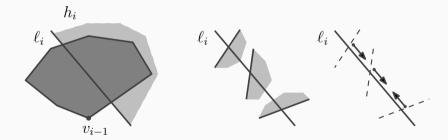

## LP for casting

### **Algorithm** LPforCasting(H)

- 1. Let  $h_1$ ,  $h_2$ , and  $v_2$  be as chosen
- 2. **for**  $i \leftarrow 3$  **to** n
- 3. **do if**  $v_{i-1} \in h_i$
- 4. then  $v_i \leftarrow v_{i-1}$
- 5. **else**  $v_i \leftarrow$  the point p on  $\ell_i$  that minimizes y, subject to the constraints in  $H_{i-1}$ .
- 6. **if** p does not exist
- 7. **then** Report that the LP is infeasible, and quit.
- 8. return  $v_n$

# LP for casting

If  $v_{i-1} \not\in h_i$ , how do we find the point p on  $\ell_i$ ?

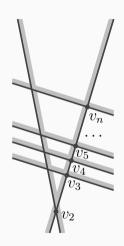

# **Efficiency**

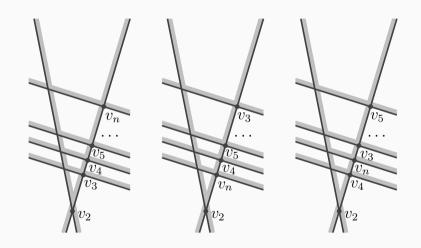

If  $v_{i-1} \in h_i$ , then the incremental step takes only O(1) time

If  $v_{i-1} \not\in h_i$ , then the incremental step takes O(i) time

The LP-for-casting algorithm takes  $O(n^2)$  time in the worst case

# **Efficiency**

# Linear programming in 2D

Randomization

## Randomized algorithm

### **Algorithm** RandomizedLPforCasting(H)

- 1. Let  $h_1$ ,  $h_2$ , and  $v_2$  be as chosen
- 2. Let  $h_3, h_4, \ldots, h_n$  be in a random order
- 3. **for**  $i \leftarrow 3$  **to** n
- 4. do if  $v_{i-1} \in h_i$
- 5. **then**  $v_i \leftarrow v_{i-1}$
- 6. **else**  $v_i \leftarrow$  the point p on  $\ell_i$  that minimizes y, subject to the constraints in  $H_{i-1}$ .
- 7. **if** p does not exist
- 8. **then** Report that the LP is infeasible, and quit.
- 9. **return**  $v_n$

## **Putting in random order**

The constraints may be given in any order, the algorithm will just reorder them

- Let j be a random integer in  $\left[3,n\right]$
- Swap  $h_j$  and  $h_n$
- Recursively shuffle  $h_3,\ldots,h_{n-1}$

Putting in random order takes O(n) time

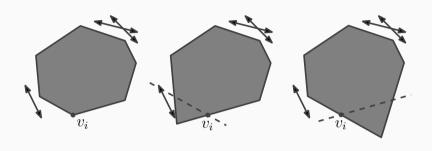

Every one of the (n-2)! orders is equally likely

The expected time taken by the algorithm is the *average* time over all orders

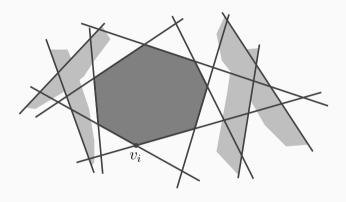

$$\frac{1}{(n-2)!} \cdot \sum_{\Pi \text{ permutation}} \text{time if the random order is } \Pi$$

If the order of the constraints  $h_3,\dots,h_n$  is random, what is the probability that  $v_{i-1}\in h_i$  ?

We use backwards analysis: consider the situation after  $h_i$  is inserted, and  $v_i$  is computed (either by  $v_i = v_{i-1}$ , or somewhere on  $\ell_i$ )

Only if one of the dashed lines was  $\ell_i$ , the last step where  $h_i$  was added was expensive and took  $\Theta(i)$  time

If  $h_i$  does not bound the feasible region, or not at  $v_i$ , then the addition step was cheap and took  $\Theta(1)$  time

There are i half-planes that could have been one of the lines defining  $v_i$ , and i-2 of these are in random order

Since the order was random, each of the i-2 half-planes has the same probability to be the last one added, and only  $\leq 2$  of these caused the expensive step

- $\leq 2$  out of i-2 cases: expensive step;  $\Theta(i)$  time for i-th addition
- $\geq$  i-4 out of i-2 cases: cheap step;  $\Theta(1)$  time for i-th addition

Expected time for i-th addition at most:

$$\frac{i-4}{i-2} \cdot \Theta(1) + \frac{2}{i-2} \cdot \Theta(i) = \Theta(1)$$

Total running time:

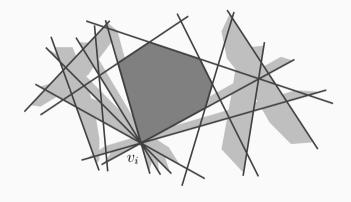

$$\Theta(n) + \sum_{i=3}^n \Theta(1) = \Theta(n)$$
 expected time

#### **Degenerate cases**

The optimal solution may not be unique, if the feasible region is bounded from below by a horizontal line. How to solve it?

There may be many lines from  $\ell_3, \dots, \ell_i$  passing through  $v_i$ ; how does this affect the probability of an expensive step?

# **Degenerate cases**

### **Degenerate cases**

In degenerate cases, the probability that the last addition was expensive is even smaller:  $1/(i-2),\,{\rm or}\ 0$ 

Without any adaptations, the running time holds

#### Result

**Theorem:** Castability of a simple polyhedron with n facets, given a top facet, can be decided in O(n) expected time

**Theorem:** 2-dimensional linear programming with n constraints can be solved in O(n) expected time

**Question:** What does "expected time" mean? Expectation over what?

## **Higher dimensions?**

**Question:** Can you imagine whether we can also solve 3-dimensional linear programming efficiently?
