Perspective projection

We get our 3D objects perspective correct on the 2D screen by applying a sequence of matrix operations.

; st3 brdf = SampleDiffuse(diffuse, N, r1, r2, 4R, 4set) prvive; pdf; n = E * brdf * (dot(N, R) / pdf);

at weight = Mis2(directPdf, brdfPdf

andom walk - done properly, closely for

st cosThetaOut = dot(N, L); E * ((weight * cosThetaOut) / directPdf

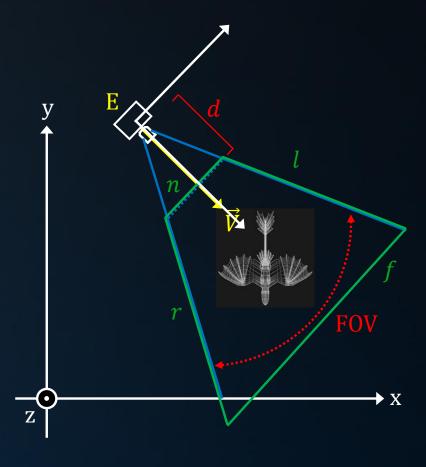

Perspective projection

The camera is defined by:

- Its position E
- The view direction \vec{V}
- The image plane (defined by its distance d and the field of view)

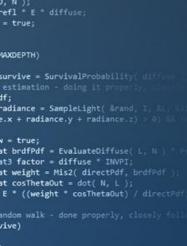

The *view frustum* is the volume visible from the camera. It is defined by:

- A near and a far plane n and f;
- A left and a right plane l and r;
- A top and a bottom plane t and b (in 3D).

The world according to the camera:

Camera space

ot3 brdf = SampleDiffuse(diffuse, N, r1, r2, ER,

1 = E * brdf * (dot(N, R) / pdf);

Perspective projection

Camera space: looking down negative *z*.

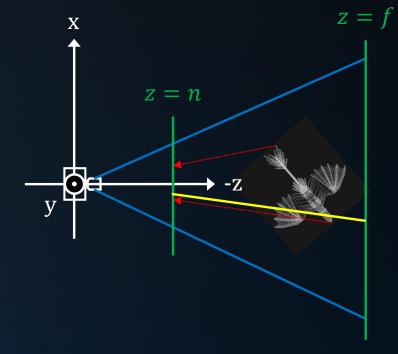

We can now map from (x, y, z) to (x_s, y_s) (but this mapping is not trivial)

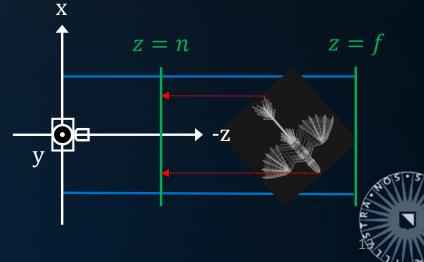

Projection (and later: clipping) becomes easier when we switch to an *orthographic* view volume.

This time the mapping is:

$$(x, y, z) \rightarrow (x, y) \rightarrow (x_s, y_s).$$

Going from camera space to the orthographic view volume can be achieved using a matrix multiplication.

efl * E * diffuse;

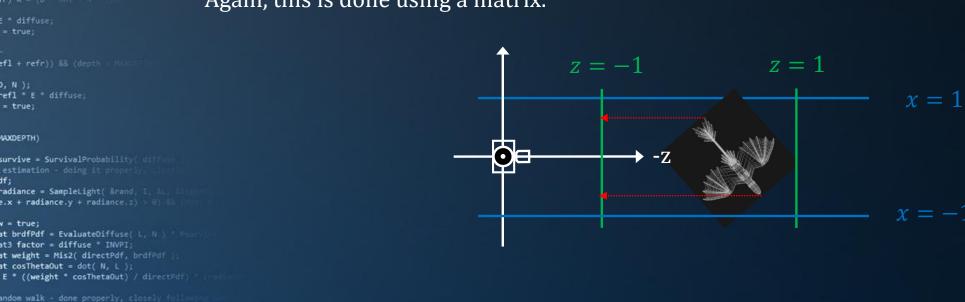

at3 brdf = SampleDiffuse(diffuse, N, r1, r2, UR, Up

1 = E * brdf * (dot(N, R) / pdf);

Perspective projection

The final transform is the one that takes us from the orthographic view volume to the canonical view volume.

Again, this is done using a matrix.

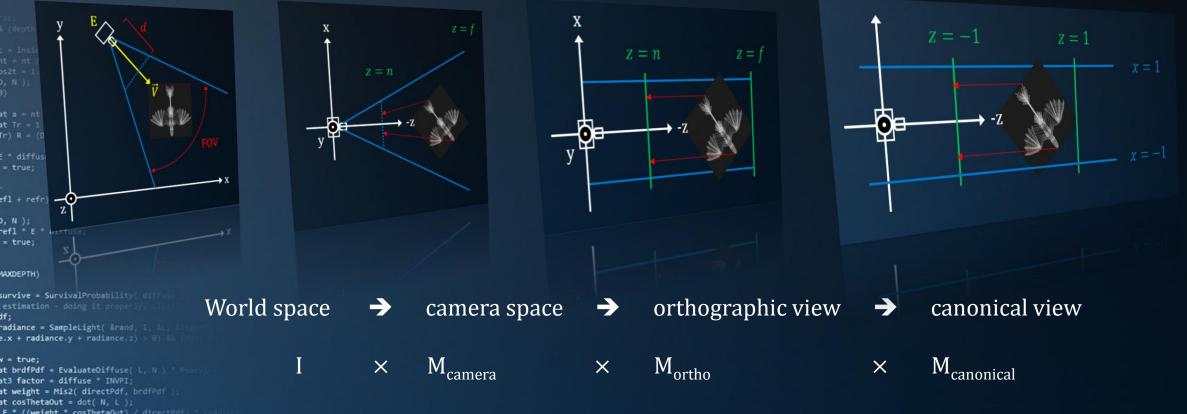

at3 brdf = SampleDiffuse(diffuse, N, r1, r2, UR, N)

= E * brdf * (dot(N, R) / pdf);

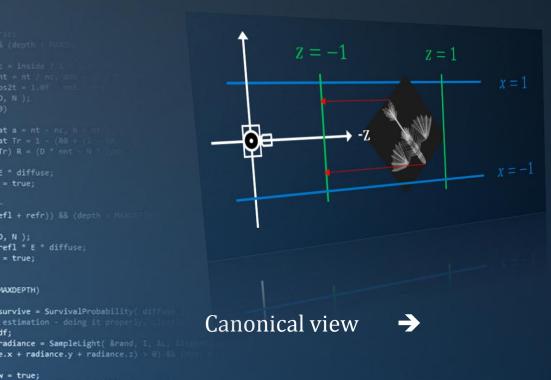

Perspective projection

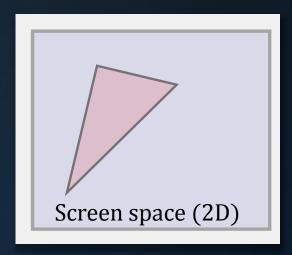

These can be collapsed into a single 4×4 matrix.

Perspective projection

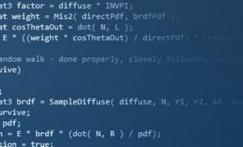

We need one last transform:

From canonical view (-1..1) to 2D screen space $(N_x \times N_y)$.

screen

at brdfPdf = EvaluateDiffuse(L, N)

Perspective projection

STEP ONE: canonical view to screen space

Vertices in the canonical view are orthographically projected on an $n_x \times n_y$ image.

We need to map the square $[-1,1]^2$ onto a rectangle $[0, n_x] \times [0, n_y]$. Matrix:

$$\begin{pmatrix} \frac{n_x}{2} & 0 & \frac{n_x}{2} \\ 0 & \frac{n_y}{2} & \frac{n_y}{2} \\ 0 & 0 & 1 \end{pmatrix}$$

This is assuming we already threw away z to get an orthographic projection. We will however combine all matrices in the end, so we actually need a 4×4 matrix:

$$M_{vp} = egin{pmatrix} rac{n_x}{2} & 0 & 0 & rac{n_x}{2} \ 0 & rac{n_y}{2} & 0 & rac{n_y}{2} \ 0 & 0 & 1 & 0 \ 0 & 0 & 0 & 1 \end{pmatrix}$$

```
andom walk - done properly, closely following wive)

ists brdf = SampleDiffuse( diffuse, N, r1, r2, &R, & urvive;
pdf;
n = E * brdf * (dot( N, R ) / pdf);
sion = true:
```

st weight = Mis2(directPdf, brdfPdf st cosThetaOut = dot(N, L);

E * ((weight * cosThetaOut) / directPdf

efl * E * diffuse;

Perspective projection

STEP ONE: canonical view to screen space

We now know the final transform for the vertices:

$$egin{pmatrix} x_{screen} \ y_{screen} \ z_{canonical} \ 1 \end{pmatrix} = M_{vp} egin{pmatrix} x_{canonical} \ y_{canonical} \ z_{canonical} \ 1 \end{pmatrix}$$

Next step: getting from the orthographic view volume to the canonical view volume.

```
st weight = Mis2( directPdf, brdfPdf );
st cosThetaOut = dot( N, L );
E * ((weight * cosThetaOut) / directPdf) * (radian
sndom walk - done properly, closely following solution)
;
st3 brdf * SampleDiffuse( diffuse, N, r1, r2, LR, b)
urvive;
pdf;
n = E * brdf * (dot( N, R ) / pdf);
sion = true;
```

efl + refr)) && (depth

survive = SurvivalProbability(dif

radiance = SampleLight(&rand, I. e.x + radiance.y + radiance.z) > 0

nt brdfPdf = EvaluateDiffuse(L, N) nt3 factor = diffuse " INVPI:

efl * E * diffuse;

), N);

= true;

MAXDEPTH)

v = true;

Perspective projection

STEP TWO: orthographic view volume to canonical view volume

The orthographic view volume is an axis aligned box $[l,r] \times [b,t] \times [n,f]$. We want to scale this to a $2 \times 2 \times 2$ box centered around the origin.

Scaling to [-1,1]:

Moving the center to the origin:

Combined:

urvive; pdf; n = E * brdf * (dot(N, R) / pdf);

), N);

= true;

efl * E * diffuse;

Perspective projection

STEP TWO: orthographic view volume to canonical view volume

The final transforms for the vertices are thus:

$$egin{pmatrix} x_{screen} \ y_{screen} \ z_{canonical} \ 1 \end{pmatrix} = M_{vp} M_{canonical} egin{pmatrix} x_{ortho} \ y_{ortho} \ z_{ortho} \ 1 \end{pmatrix}$$

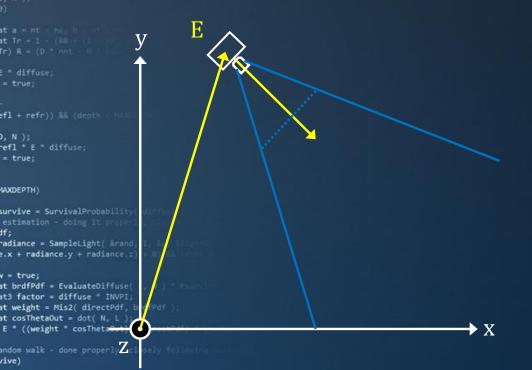

Next step: getting from camera space to the orthographic view volume.

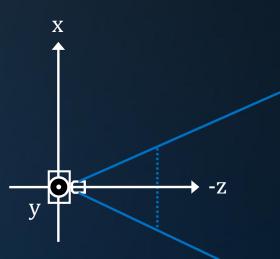

```
), N );
efl * E * diffuse;
MAXDEPTH)
survive = SurvivalProbability( diff
adiance = SampleLight( &rand, I.
e.x + radiance.y + radiance.z) > 0
v = true;
at brdfPdf = EvaluateDiffuse( L, N )
st3 factor = diffuse * INVPI:
st weight = Mis2( directPdf, brdfPdf
at cosThetaOut = dot( N, L );
E * ((weight * cosThetaOut) / directPdf)
andom walk - done properly, closely fello
ot3 brdf = SampleDiffuse( diffuse, N, r1, r2, R, );
```

1 = E * brdf * (dot(N, R) / pdf);

Perspective projection

STEP THREE: camera space to orthographic view volume

Translate:

$$egin{pmatrix} 1 & 0 & 0 & -E_x \ 0 & 1 & 0 & -E_y \ 0 & 0 & 1 & -E_z \ 0 & 0 & 0 & 1 \end{pmatrix}$$

i.e., the inverse of the camera translation.

Rotate:

We will use the inverse of the basis defined by the camera orientation.

;
st3 brdf = SampleDiffuse(diffuse, N, r1, r2, ER, bpd)
urvive;
pdf;
n = E * brdf * (dot(N, R) / pdf);

fl + refr)) && (depth

survive = SurvivalProbability(dif

st weight = Mis2(directPdf, brdfPdf st cosThetaOut = dot(N, L);

E * ((weight * cosThetaOut) / directPdf)
andom walk - done properly, closely follo

efl * E * diffuse;

), N);

= true;

Perspective projection

STEP THREE: camera space to orthographic view volume

Basis defined by the camera orientation:

z-axis: $-\vec{V}$ (convention says we look down -z)

x-axis: $-\vec{V} \times \overrightarrow{up}$

y-axis: $\vec{V} \times \vec{x}$

Matrix:

Inverse:

$$\begin{pmatrix} X_x & Y_x & -V_x & 0 \\ X_y & Y_y & -V_y & 0 \\ X_z & Y_z & -V_z & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

$$\begin{pmatrix} X_x & X_y & X_z & 0 \\ Y_x & Y_y & Y_z & 0 \\ -V_x & -V_y & -V_z & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

$$\vec{z}$$
 \vec{x}
 \vec{v}

$$\begin{pmatrix} 1 & 0 & 0 & -E_x \\ 0 & 1 & 0 & -E_y \\ 0 & 0 & 1 & -E_z \\ 0 & 0 & 0 & 1 \end{pmatrix} = M_{camera}$$

;

st3 brdf = SampleDiffuse(diffuse, N, r1, r2, &R, appropriate);

prvive;

pdf;

n = E * brdf * (dot(N, R) / pdf);

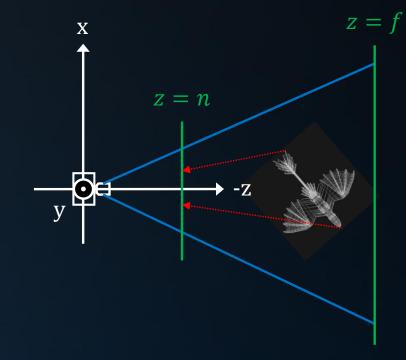

Perspective projection

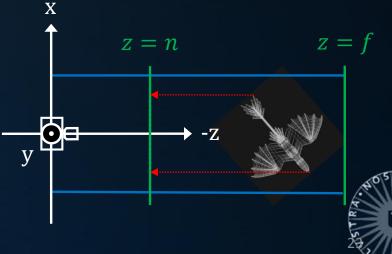

STEP THREE: camera space to orthographic view volume

The combined transform so far:

$$\begin{pmatrix} x_{screen} \\ y_{screen} \\ z_{canonical} \end{pmatrix} = M_{vp} M_{canonical} M_{camera} \begin{pmatrix} x_{world} \\ y_{world} \\ z_{world} \\ 1 \end{pmatrix}$$

One thing is still missing: perspective.

), N);

Perspective projection

Q: What is perspective?

A: The size of an object on the screen is proportional to 1/z.

More precisely:

$$y_S = \frac{d}{z}y$$
 (and $x_S = \frac{d}{z}x$)

where d is the distance of the view plane to the camera.

Q: How do we capture scaling based on distance in a matrix? A: ...

Dividing by z can't be done using linear nor affine transforms.

andom walk - done properly, closely follo

efl * E * diffuse;

), N);

= true;

Perspective projection

Let's have a look at homogeneous coordinates again.

Recall:

$$\begin{pmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} a_1 x + b_1 y + c_1 z \\ a_2 x + b_2 y + c_2 z \\ a_3 x + b_3 y + c_3 z \end{pmatrix}$$

With homogeneous coordinates, we get:

$$\begin{pmatrix} a_1 & b_1 & c_1 & T_x \\ a_2 & b_2 & c_2 & T_y \\ a_3 & b_3 & c_3 & T_z \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} = \begin{pmatrix} a_1x + b_1y + c_1z + T_x \\ a_2x + b_2y + c_2z + T_y \\ a_3x + b_3y + c_3z + T_z \end{pmatrix} = \begin{pmatrix} (a_1x + b_1y + c_1z + T_x)/1 \\ (a_2x + b_2y + c_2z + T_y)/1 \\ (a_3x + b_3y + c_3z + T_z)/1 \\ 1 \end{pmatrix}$$

;

st3 brdf = SampleDiffuse(diffuse, N, r1, r2, UR, upd irvive;

pdf;

n = E * brdf * (dot(N, R) / pdf);

Perspective projection

$$\begin{pmatrix} \tilde{x} \\ \tilde{y} \\ \tilde{z} \\ \tilde{w} \end{pmatrix} = \begin{pmatrix} a_1 & b_1 & c_1 & T_x \\ a_2 & b_2 & c_2 & T_y \\ a_3 & b_3 & c_3 & T_z \\ a_4 & b_4 & c_4 & w \end{pmatrix} \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} = \begin{pmatrix} a_1x + b_1y + c_1z + T_x \\ a_2x + b_2y + c_2z + T_y \\ a_3x + b_3y + c_3z + T_z \\ a_4x + b_4y + c_4z + w \end{pmatrix}$$

Recall that using homogeneous coordinates (x, y, z, 1) represents (x, y, z).

The homogeneous vector (x, y, z, w) represents $\left(\frac{x}{w}, \frac{y}{w}, \frac{z}{w}\right)$.

The division by *w* is called *homogenization*.

Notice that this doesn't change any part of our framework, where w=1.

```
st3 factor = diffuse " INVPI;
st weight = Mis2( directPdf, brdfPdf );
st cosThetaOut = dot( N, L );
E * ((weight * cosThetaOut) / directPdf) * (Public
sindom walk - done properly, closely following and
vive)

st3 brdf * SampleDiffuse( diffuse, N, r1, r2, LR, L
urvive;
pdf;
n = E * brdf * (dot( N, R ) / pdf);
sion = true;
```

efl + refr)) && (depth

survive = SurvivalProbability diff

radiance = SampleLight(&rand, I, Al e.x + radiance.y + radiance.z) > 0)

at brdfPdf = EvaluateDiffuse(L. N)

efl * E * diffuse;

), N);

= true;

MAXDEPTH)

v = true;

efl + refr)) && (depth of

st weight = Mis2(directPdf, brdfPdf st cosThetaOut = dot(N, L);

= E * brdf * (dot(N, R) / pdf);

E * ((weight * cosThetaOut) / directPdf)
andom walk - done properly, closely folio

ot3 brdf = SampleDiffuse(diffuse, N, r1, r2, UR

efl * E * diffuse;

), N);

= true;

Perspective projection

So, multiplying by this matrix

$$\begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} \times \begin{pmatrix} a_1 & b_1 & c_1 & T_x \\ a_2 & b_2 & c_2 & T_y \\ a_3 & b_3 & c_3 & T_z \\ a_4 & b_4 & c_4 & w \end{pmatrix}$$

and homogenization, creates this vector:

$$\begin{pmatrix} (a_1x + b_1y + c_1z + Tx) / (a_4x + b_4y + c_4z + w) \\ (a_2x + b_2y + c_2z + Ty) / (a_4x + b_4y + c_4z + w) \\ (a_3x + b_3y + c_3z + Tz) / (a_4x + b_4y + c_4z + w) \\ 1 \end{pmatrix}$$

How do we chose the coefficients of the matrix so that we get correct perspective correction?

I.e., something like this:

$$\begin{pmatrix} nx/z \\ ny/z \\ z \\ 1 \end{pmatrix}$$

Perspective projection

The matrix we are looking for is:

$$\left(\begin{array}{ccc} 0 & n & 0 & 0 \\ 0 & 0 & n+f & -fn \end{array}\right) \left(\begin{array}{c} y \\ z \end{array}\right) =$$

$$\begin{pmatrix} n & 0 & 0 & 0 \\ 0 & n & 0 & 0 \\ 0 & 0 & n+f & -fn \\ 0 & 0 & 1 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} = \begin{pmatrix} nx \\ ny \\ (n+f)z - fn \\ z \end{pmatrix} \quad \xrightarrow{\text{homogenize}} \quad \begin{pmatrix} nx/z \\ ny/z \\ n+f-fn/z \\ 1 \end{pmatrix}$$

$$\begin{pmatrix} nx/z \\ ny/z \\ n+f-fn/z \\ 1 \end{pmatrix}$$

Let's verify.

What happened to
$$z$$
? \Rightarrow $z' = n + f - \frac{fn}{z}$

- z = n: z' = n
- $z = f \colon z' = f$
- All other z yield values between n and f (but: proportional to $\frac{1}{z}$).

```
ot3 brdf = SampleDiffuse( diffuse, N, r1, r2, 4R,
= E * brdf * (dot( N, R ) / pdf);
```

adiance = SampleLight(&rand, I.

at brdfPdf = EvaluateDiffuse(L. N)

Animation, culling, tessellation, ...

Postprocessing

Transformations

World space to screen space:

$$\begin{pmatrix} x_{screen} \\ y_{screen} \\ z_{canonical} \\ 1 \end{pmatrix} = M_{vp} M_{perspective} M_{camera} \begin{pmatrix} x_{world} \\ y_{world} \\ z_{world} \\ 1 \end{pmatrix}$$

Object space to world space:

$$\begin{pmatrix} x_{world} \\ y_{world} \\ z_{world} \\ 1 \end{pmatrix} = M_{local} M_{parent} \begin{pmatrix} x_{local} \\ y_{local} \\ z_{local} \\ 1 \end{pmatrix}$$

In all cases, we construct a *single* 4×4 matrix, which we then apply to all vertices of a mesh.

Animation, culling, tessellation, ...

meshes

pixels

Postprocessing

;
st3 brdf = SampleDiffuse(diffuse, N, r1, r2, ER, E
urvive;
pdf;
n = E * brdf * (dot(N, R) / pdf);

Transformations

Rendering a scene graph is done using a recursive function:

```
void SGNode::Render( mat4& M )
{
    mat4 M' = M<sub>local</sub> * M;
    mesh->Rasterize( M' );
    for( int i = 0; i < childCount; i++ )
        child[i]->Render( M' );
};
```

Here, matrix concatenation is part of the recursive flow.

```
st brdfPdf = EvaluateDiffuse( L, N ) * Paurolists
st3 factor = diffuse * INVPI;
st weight = Mis2( directPdf, brdfPdf );
st cosThetaOut = dot( N, L );

sindom walk - done properly, closely felloward
vive)

st3 brdf = SampleDiffuse( diffuse, N, r1, r2, RR, Rp
urvive;
pdf;
i = E * brdf * (dot( N, R ) / pdf);
sion = true;
```

fl + refr)) && (depth

survive = SurvivalProbability diff

adiance = SampleLight(&rand, I.

e.x + radiance.y + radiance.z) > 0

efl * E * diffuse;

), N);

MAXDEPTH)

v = true;

Transformations

To transform meshes to world space, we call SGNode::Render with an identity matrix.

To transform meshes to camera space, we call it with the *inverse* transform of the camera.

Remember: the world revolves around the viewer; instead of turning the viewer, we turn the world in the opposite direction.

```
void SGNode::Render( mat4& M )

After projection

The output of the projection stage is a stream of vertices for which we know 2D screen positions.

The vertex stream must be combined with connectivity data to form triangles.

'Triangles' on a raster consist of a collection of pixels, called *fragments*.

connectivity data

Today's Agenda:

- Projection
- Pipeline Recap
- Rasterization

```

Connectivity data

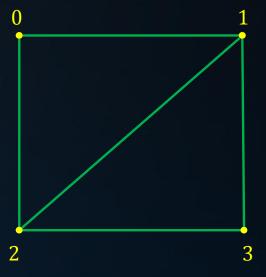

Two triangles forming a quad, using four vertices:

0 1	2	1	3	2
-----	---	---	---	---

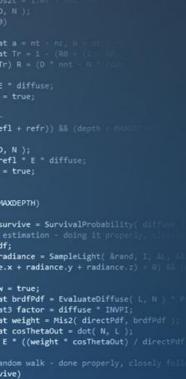

Note:

- Connectivity data has no relation to actual vertex positions.
- Triangles are typically defined in clockwise order around the triangle normal.

These two notes can be contradictory, but in practice, they rarely are.

ot3 brdf = SampleDiffuse(diffuse, N, r1, r2, NR, N

= E * brdf * (dot(N, R) / pdf);

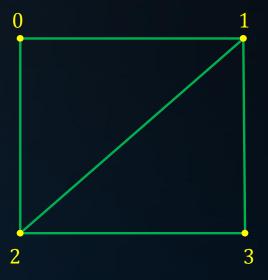

Connectivity data

We can store triangles more efficiently using triangle strips.

Here, the first three vertex indices specify the first triangle. After that, subsequent triangles use the previous two indices, plus one extra vertex.

It is rarely possible to define a complete mesh using a single triangle strip. However, we can generally reduce a mesh to a small set of strips.

On modern hardware, triangle strips are rarely used:

- The memory reduction affects only the connectivity data, which is small compared to vertex data;
- Multiple strips for a single mesh may incur significant overhead in the driver.

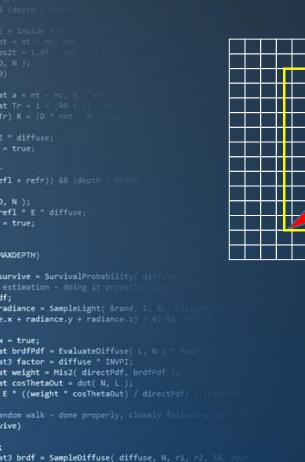

Triangle rasterization

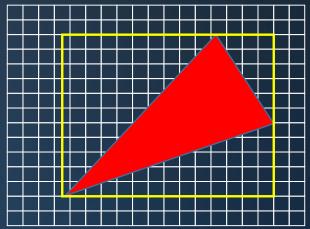

Triangle rasterization

1 = E * brdf * (dot(N, R) / pdf);

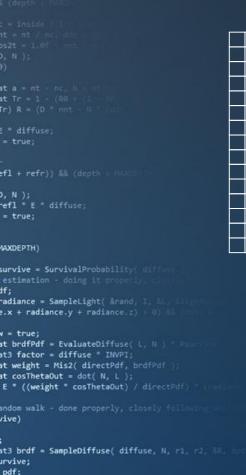

Rasterizing a triangle, method 1: *(from the book, 8.1.2)*

- 1. Determine the axis-aligned bounding box of the triangle;
- 2. For each pixel within this box, determine whether it is inside the triangle.

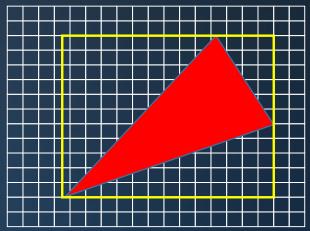

Drawback: at least 50% of the pixels will be rejected.

Triangle rasterization

1 = E * brdf * (dot(N, R) / pdf);

Rasterizing a triangle, method 2: (see e.g. fatmap.txt, fatmap2.txt)

- 1. Per scanline (within the bounding box), determine the left and right side of the triangle;
- 2. Per scanline, draw a horizontal line from the left to the right.

Drawback: not as easy to execute in parallel on GPUs.

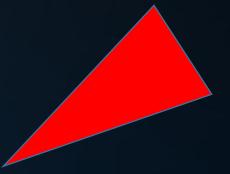

Triangle rasterization

So far, we have seen how to fill a triangle, or more accurately: how to determine which pixels it overlaps.

To shade the triangle, we need more information.

Per pixel:

- Color (e.g. from a texture);
- Normal;
- Interpolated per-vertex shading information.

efl + refr)) && (depth

radiance = SampleLight(&rand, I, Al e.x + radiance.y + radiance.z) > 0)

efl * E * diffuse;

), N);

MAXDEPTH)

v = true;

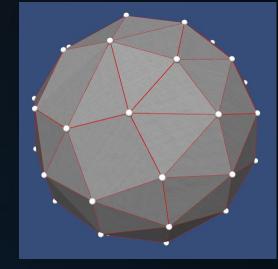

Sanity check

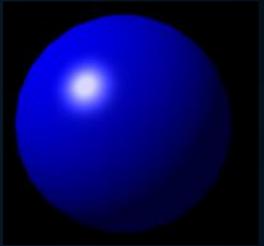

Let's take a brief moment to meditate on the madness on the previous slide.

Per pixel:

Normal

A triangle is defined by three vertices. All points on the triangle lie in the same plane. Therefore, the normal for each point on the triangle is the same.

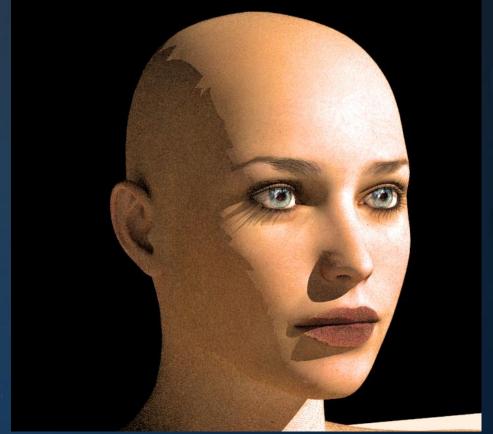

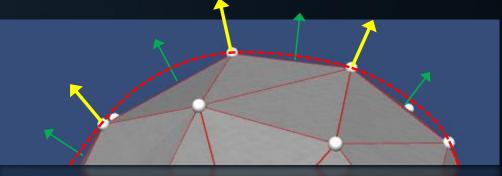

Sanity check

Normal interpolation can cause some bad behavior:

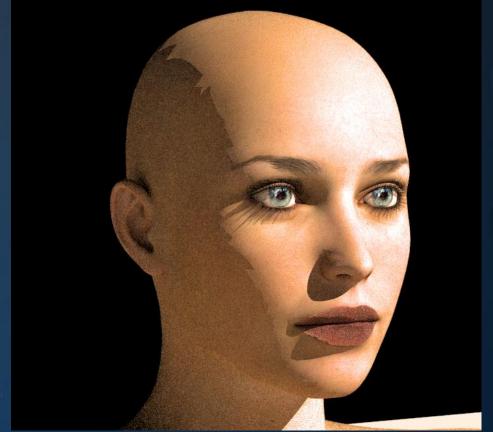

Shadows are still cast by the not-so-smooth geometry.

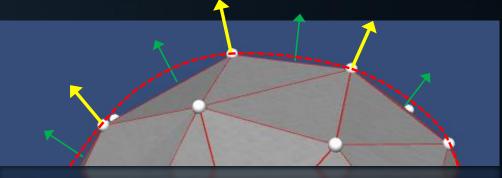

Sanity check

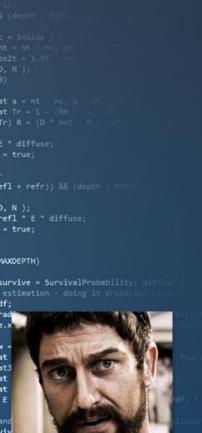

Normal interpolation can cause some bad behavior:

Shadows are still cast by the not-so-smooth geometry.

Sanity check

Shading interpolation:

Normal interpolation is costly: a linearly interpolated normal needs normalization, which involves a square root.

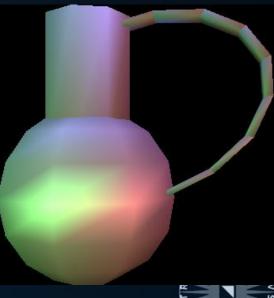

Solution: calculate shading per vertex, and interpolate.

solution. Calculate shaumg per vertex, and interpolate

Sanity check

Shading:

In nature, the color of a surface is the sum of all the light reflected by the surface towards the camera.

Incoming light:

- Direct light (arriving from light sources);
- Indirect light (arriving via other surfaces).

Incoming light is partially absorbed, partially reflected. Light is generally not reflected uniformly in all directions.

Triangle rasterization

Interpolating per-vertex values over a triangle:

Barycentric coordinates.

Any point on the triangle can be parameterized by two values:

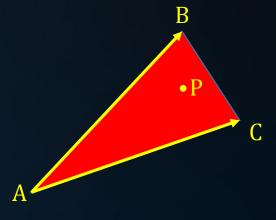

$$P(\lambda_1, \lambda_2) = A + \lambda_1(B - A) + \lambda_2(C - A)$$

where $0 \le \lambda_1$, $\lambda_2 \le 1$, and $\lambda_1 + \lambda_2 \le 1$.

Or, reversed:

$$\lambda_1 = P \cdot (B - A) - P \cdot A$$

$$\lambda_2 = P \cdot (C - A) - P \cdot A$$

sndom walk - done properly, closely fellowing

survive = SurvivalProbability(dlf

adiance = SampleLight(&rand, I.

st weight = Mis2(directPdf, brdfPdf); st cosThetaOut = dot(N, L); E * ((weight * cosThetaOut) / directPdf

MAXDEPTH)

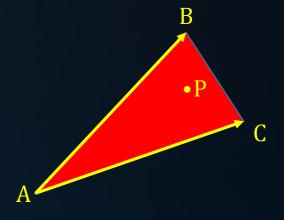

Triangle rasterization

$$P(\lambda_1, \lambda_2) = A + \lambda_1(B - A) + \lambda_2(C - A)$$

Given the vertex normals N_A , N_B and N_C , we can now calculate the interpolated per-pixel normal N_P :

$$N_P = N_A + \lambda_1 (N_B - N_A) + \lambda_2 (N_C - N_A)$$

Remember that an interpolated normal is typically not normalized.
