Data Mining 2024 Classification Trees (1)

Ad Feelders

Universiteit Utrecht

æ

イロン イ理 とく ヨン イ ヨン

Predict the class of an object on the basis of some of its attributes. For example, predict:

- Good/bad credit for loan applicants, using
 - income
 - age
 - ...
- Spam/no spam for e-mail messages, using
 - % of words matching a given word (e.g. "free")
 - use of CAPITAL LETTERS
 - ...
- Music Genre (Rock, Techno, Death Metal, ...) based on audio features and lyrics.

(日)

The basic idea is to build a classification model using a set of training examples. Each training example contains attribute values and the corresponding class label.

There are many techniques to do that:

- Statistical Techniques
 - Discriminant Analysis
 - Logistic Regression
- Data Mining/Machine Learning
 - Classification Trees
 - Bayesian Network Classifiers
 - Neural Networks
 - Support Vector Machines
 - ...

< ロ > < 同 > < 回 > < 回 > < 回 > <

Strong and Weak Points of Classification Trees

Strong points:

- Are easy to interpret (if not too large).
- Select relevant attributes automatically.
- Can handle both numeric and categorical attributes.

Weak point:

• Single trees are usually not among the top performers.

However:

- Averaging multiple trees (bagging, boosting, random forests) can bring them back to the top!
- But ease of interpretation suffers as a consequence.

Why not split on gender in the root node?

Intuitively: learning the value of gender doesn't provide much information about the class label.

3

イロト 不得 トイヨト イヨト

- We strive towards nodes that are *pure* in the sense that they only contain observations of a single class.
- We need a measure that indicates "how far" a node is removed from this ideal.
- We call such a measure an *impurity* measure.

イロト イヨト イヨト ・

Impurity function

The impurity i(t) of a node t is a function of the relative frequencies of the classes in that node:

$$i(t) = \phi(p_1, p_2, \ldots, p_J)$$

where the $p_j(j = 1, ..., J)$ are the relative frequencies of the J different classes in node t.

Sensible requirements of any quantification of impurity:

- Should be at a maximum when the observations are distributed evenly over all classes.
- Should be at a minimum when all observations belong to a single class.
- Should be a symmetric function of p_1, \ldots, p_J .

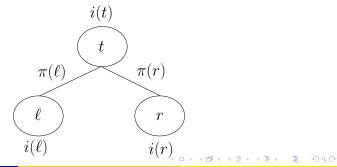

イロト イヨト イヨト イヨト 二日

Quality of a split (test)

We define the quality of binary split s in node t as the *reduction* of impurity that it achieves

$$\Delta i(s,t) = i(t) - \{\pi(\ell)i(\ell) + \pi(r)i(r)\}$$

where ℓ is the left child of t, r is the right child of t, $\pi(\ell)$ is the proportion of cases sent to the left, and $\pi(r)$ the proportion of cases sent to the right.

Impurity functions we consider:

- Resubstitution error
- Gini-index
- Entropy

э

イロト イポト イヨト イヨト

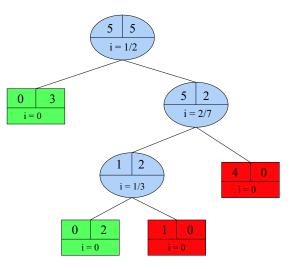

Measures the fraction of cases that is classified incorrectly if we assign every case in node t to the majority class in that node. That is

$$i(t) = 1 - \max_j p(j|t)$$

where p(j|t) is the relative frequency of class j in node t.

Which split is better?

These splits have the same resubstitution error, but s_2 is commonly preferred because it creates a leaf node.

э

イロト 不得 トイヨト イヨト

Class of suitable impurity functions

- Problem: resubstitution error only decreases at a *constant* rate as the node becomes purer.
- We need an impurity measure which gives greater rewards to purer nodes. Impurity should decrease at an *increasing* rate as the node becomes purer.
- Hence, impurity should be a strictly *concave* function of p(0).

We define the class \mathcal{F} of impurity functions (for two-class problems) that has this property:

• $\phi(0) = \phi(1) = 0$ (minimum at p(0) = 0 and p(0) = 1)

2
$$\phi(p(0)) = \phi(1 - p(0))$$
 (symmetric)

3 $\phi''(p(0)) < 0, 0 < p(0) < 1$ (strictly concave)

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

For the two-class case the Gini index is

$$i(t) = p(0|t)p(1|t) = p(0|t)(1-p(0|t))$$

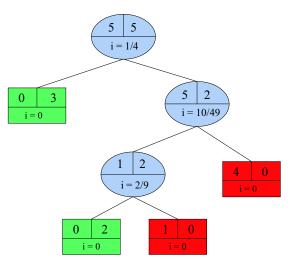

Question 1: Check that the Gini index belongs to \mathcal{F} .

Question 2: Check that if we use the Gini index, split s_2 is indeed preferred.

Note: The variance of a Bernoulli random variable with probability of success p is p(1 - p). Hence we are attempting to minimize the variance of the class distribution.

Can impurity increase?

A concave function g. For any x and y, the line segment connecting g(x) and g(y) is below the graph of g. $z = \alpha x + (1 - \alpha)y$.

$$g(\alpha x + (1 - \alpha)y) \ge \alpha g(x) + (1 - \alpha)g(y)$$

Is it possible that a split makes things worse, i.e. $\Delta i(s, t) < 0$?

Not if $\phi \in \mathcal{F}$. Because ϕ is a concave function, we have

 $\phi(p(0|\ell)\pi(\ell) + p(0|r)\pi(r)) \ge \pi(\ell)\phi(p(0|\ell)) + \pi(r)\phi(p(0|r))$

Since

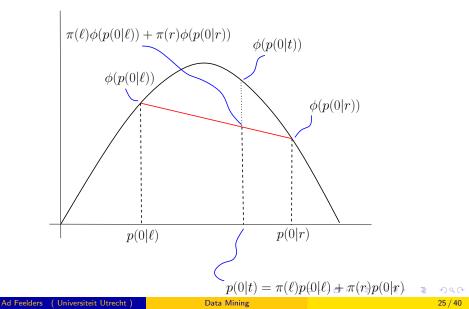

$$p(0|t) = p(0|\ell)\pi(\ell) + p(0|r)\pi(r)$$

it follows that

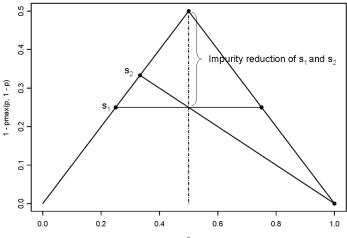

$$\phi(p(0|t)) \geq \pi(\ell)\phi(p(0|\ell)) + \pi(r)\phi(p(0|r))$$

æ

Split s_1 and s_2 with Gini

27 / 40

æ

For the two-class case the entropy is

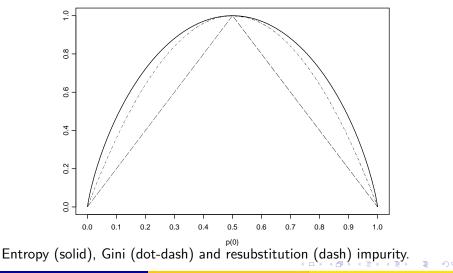

$$i(t) = -p(0|t) \log p(0|t) - p(1|t) \log p(1|t)$$

Question: Check that entropy impurity belongs to \mathcal{F} .

Remark: this is the average amount of information generated by drawing (with replacement) an example at random from this node, and observing its class.

- 4 回 ト 4 ヨ ト 4 ヨ ト

Three (rescaled) impurity measures

- Seach split depends on the value of only a *single* attribute.
- If attribute x is numeric, we consider all splits of type x ≤ c where c is (halfway) between two consecutive values of x in their sorted order.
- If attribute x is categorical, taking values in {b₁, b₂,..., b_L}, we consider all splits of type x ∈ S, where S is any non-empty proper subset of {b₁, b₂,..., b_L}.

Splits on numeric attributes

There is only a finite number of distinct splits, because there are at most n distinct values of a numeric attribute in the training sample (where n is the number of examples in the training sample).

Example: possible splits on income in the root for the loan data

Income	Class	Quality (split after)
		0.25-
24	В	0.1(1)(0)+0.9(4/9)(5/9)=0.03
27	В	0.2(1)(0) + 0.8 (3/8)(5/8) = 0.06
28	B,G	0.4(3/4)(1/4) + 0.6(2/6)(4/6) = 0.04
30	G	0.5(3/5)(2/5) + 0.5(2/5)(3/5) = 0.01
32	B,B	0.7(5/7)(2/7) + 0.3(0)(1) = 0.11
40	G	0.8(5/8)(3/8) + 0.2(0)(1) = 0.06
52	G	0.9(5/9)(4/9) + 0.1(0)(1) = 0.03
58	G

For a categorical attribute with L distinct values there are $2^{L-1} - 1$ distinct splits to consider. Why?

3

イロト 不得 トイヨト イヨト

For a categorical attribute with L distinct values there are $2^{L-1} - 1$ distinct splits to consider. Why?

There are $2^L - 2$ non-empty proper subsets of $\{b_1, b_2, \ldots, b_L\}$.

But a subset and the complement of that subset result in the same split, so we should divide this number by 2.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

For two-class problems, and $\phi \in \mathcal{F}$, we don't have to check all $2^{L-1} - 1$ possible splits. Sort the $p(0|x = b_{\ell})$, that is,

$$p(0|x = b_{\ell_1}) \le p(0|x = b_{\ell_2}) \le \ldots \le p(0|x = b_{\ell_L})$$

Then one of the L-1 subsets

$$\{b_{\ell_1},\ldots,b_{\ell_h}\}, \ h=1,\ldots,L-1,$$

is the optimal split. Thus the search is reduced from computing $2^{L-1} - 1$ splits to computing only L - 1 splits.

Let x be a categorical attribute with possible values a, b, c, d. Suppose

p(0|x = a) = 0.6, p(0|x = b) = 0.4, p(0|x = c) = 0.2, p(0|x = d) = 0.8

Sort the values of x according to probability of class 0

c b a d

We only have to consider the splits: $\{c\}, \{c, b\}$, and $\{c, b, a\}$.

Intuition: put values with low probability of class 0 in one group, and values with high probability of class 0 in the other.

イロト 不得 トイラト イラト 一日

Segment borders: numeric example

A segment is a block of consecutive values of the split attribute for which the class distribution is identical. Optimal splits can only occur at segment borders.

Consider the following data on numeric attribute x and class label y. The class label can take on two different values, coded as A and B.

ſ	х	8	8	12	12	14	16	16	18	20	20
	у	Α	В	А	В	А	А	А	А	А	В

The class probabilities (relative frequencies) are:

						20
P(A)	0.5	0.5	1	1	1	0.5
$\begin{array}{c} P(A) \\ P(B) \end{array}$	0.5	0.5	0	0	0	0.5

So we obtain the segments: (8, 12), (14, 16, 18) and (20). Only consider the splits: $x \le 13$ and $x \le 19$ Ignore: $x \le 10$, $x \le 15$ and $x \le 17$

イロト 不得 トイヨト イヨト 二日

- In the first practical assignment we use the parameters nmin and minleaf to stop tree growing early.
- A split is not allowed to produce a child node with less than minleaf observations.
- The segment borders algorithm doesn't combine very well with the minleaf constraint.
- Better use the "brute force" approach in the assignment.

Practical Assignment 1

- Teams of 3 students.
- Program a classification tree algorithm from scratch.
- In Python or R.
- Use of libraries for general data processing or manipulating tree data structures is allowed
 (a.g. numpulating particular data tracking P)
 - (e.g. numpy, pandas in Python, dplyr, data.tree in R).
- https://ics-websites.science.uu.nl/docs/vakken/mdm/practicum.html
- Use of generative AI tools is not allowed, except for improving the writing of the report.
- Start with "Getting started with ...".
- Computer lab in BBG, rooms 201/219/223.
